

(a) Ordinary geometric base anchor

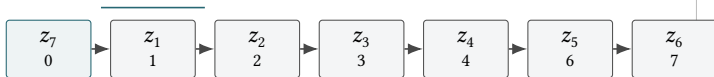

decreasing iteration $i = 7$: $z_7 = 0$, base anchor $a_7 = z_2 = 2$

This would leave $z_1 = 1$ on the wrong side of the new point.

(b) Odd-index z_1 output-anchor correction

$z_7 < z_1 < a_7$, so the output anchor changes from z_2 to z_1

corrected insertion before output anchor z_1 gives axis order (0, 1, 2, 3, 4, 6, 7)
